

## CHC Technical Conference

### DECC Solid Wall Research Project

Colin King

Part of the BRE Trust

## Content

- The project outline
- The work packages
- Major Areas of Work
- Summary

## More than just bricks

- The project aims to look at the construction types in the UK of solid wall construction that make up the largest percentage
- More than just brick properties, with overlap into other construction forms

## Work Package 1 - Literature review and data assessment

- what's already known
- heritage considerations
- understanding heat loss measurement
- un- intended consequences
- human behaviour
- solid wall performance actual v predicted

## Work Package 2 - Understanding heat losses from solid walls

- Moisture content
- Micro cavities
- Continuity of mortar
- Unknown properties of materials within structures
- Exposure
- Hot boxing and in situ measurement of a range of configurations

## Work Package 3 - Pre- and post- insulation survey: The performance gap

- What effect does the installation of solid wall insulation have on energy use behaviour in different types of dwellings?
- What are the typical energy savings that can be expected following the installation of solid wall insulation?
- What effect does it have on internal temperatures across the year? Is there evidence of overheating?

## WP 3 – Cont'd

- What effect (if any) does it have on condensation levels and mould growth?
- Are there any other effects on other indicators of air quality?
- Is there any evidence of other un-intended consequences of refurbishment (for example on the structural integrity of the building caused by damp problems)? Covered in depth WP5

## Work package 4 - Methodologies for measuring & calculating U-values

- This task will provide verification and validation of the methodology used to measure heat flux of walls *in-situ*. It consists of a number of laboratory and test-house experiments, and a summary validation report on the results of these tests including recommendations for any changes to the methodology.
- A range of testing and calibration of methods

## WP 4 Cont'd

- Tests 1a to 1e: Hot-box tests on heat flux plates
- Test 2: Reproducibility of measured U-value at a single measurement point
- Test 3: Testing the method of pressure-fixing
- Test 4: Determining the effect of sunlight:
- Test 5: Determining the effect of surface texture:
- Test 6: Effect of vertical temperature stratification on measured U-value:
- Test 7: Investigation into the effect of heat flux plate calibration and construction:

## WP 5

- A process for surveying and understanding the risks of un-intended consequences.

- Ø Systemic
- Ø Design
- Ø Human Behaviour
- Ø Environmental Conditions
- Ø Building Physics

## WP 6

- A method of measuring a u-value of a building in situ.

-

## Previous work

- Previous experience of the effect of inappropriate insulation.
- Previous experience of poorly assessed buildings being chosen for insulation
- Poor detailing on site – even if appropriate
- Understanding of the risk of insulating older properties, with many unknown factors being assumed.
- Understanding the effect of wind driven rain on buildings

# SWI Performance Unintended Consequences

## Early Findings

Part of the BRE Trust

bre

## **Work Package 5**

Unintended consequences emerging  
from previous studies

## Scope of Study

- Various locations across the UK
- Previous involvement in projects
- All external wall insulation -
- Wall Constructions various
  - Brick
  - Stone (various)
  - Concrete
  - Timber – included

## Early Findings

- Growing Evidence of
  - Wrong expertise
  - Incorrect assessment
  - Incorrect consideration of climatic conditions
  - Premature failure
  - High levels of unintended consequences
  - Standard detailing not fit for purpose
  - Workmanship often wanting

## Lampeter

- The properties within this original work consisted of a number of construction types, but all of solid wall, and a 3 build forms, houses, bungalows and flats, with 45% (75) being bungalows, 20% flats (32) and 35% (60) houses.
- All off gas, all social housing

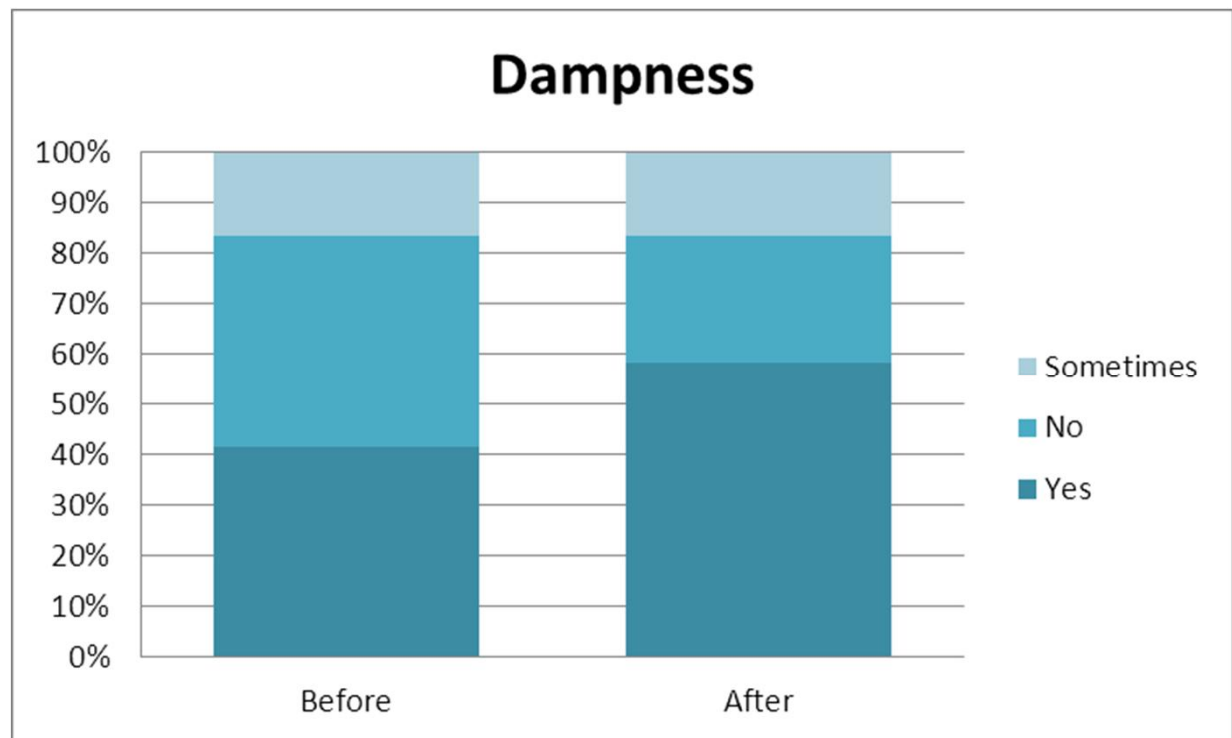

## Lampeter

- Condensation where none before, no consideration of ventilation.
- Buildings more air tight than before
- Work poorly sequenced
- Lack of detailed surveying before work undertaken

## Arbed

- Total of 37 properties analysed, only EWI

bre

## Arbed

bre

## Arbed

## Midlands

- Non insulated floor slab below plinth
- Condensation and mould in room corners

## Problems with Moisture

Timber Frame  
House

Built in 1967

Insulated in 2006

Wet rot, structural  
failure 2012

- water  
ingress

- poor  
detailing

## Solid Wall in Lake District

- 250 years old
- Completed in January of this year
- Not exposed to high winds, but in high exposure area.
- System failing and saturated
- Starting to peel off

## Workmanship – Decision to Insulate with this system ?

## Thermal Bridging Modelling

- Standard Industry approach to detailing openings
- Difficult to insulate ? so rarely done.
- Impact of in-correct detailing

Figure 1a: Baseline jamb detail

b: Baseline jamb with temperature gradations

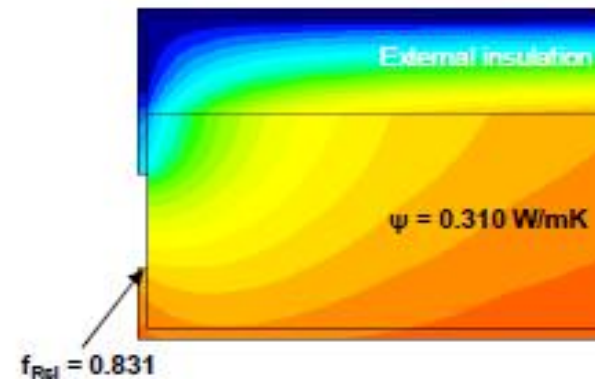

## Thermal Bridging

- Initial modelling indicates if the reveals and heads etc are not insulated the psi value of the area becomes worse than before insulated.
- Risk shifted to areas least capable of dealing with them.
- Increased heat loss, and much higher risk of condensation and mould growth / failure.

c: Jamb with 'typical' external insulation

d: Jamb with improved insulation detailing

## Example: Aluminium profile at the plinth penetrating the insulation layer

Equivalent impact to leaving out 1.80 metre high strip of insulation!

## Modelling with real climate data & wall condition

Fig. 4: Moisture transport phenomena in the pores of a massive exterior wall in winter, for different levels of moisture content

## Steady State Calculation

## Three winter days

# bre Three summer days

## Data Collection Field Trial

Real time moisture content in 4 wall constructions within 3 miles of each other

## Brick Properties – Wufi 2D

- Actual model, Manchester weather data and extensive material knowledge
- Existing performance
- Moisture in the mortar
- Surface evaporation both surfaces

## Non open fibre materials used

- Increased Rh
- Surface condensation
- Moisture trapped behind non open layer
- Risk of freeze thaw frost damage to surface predicted by year 7, toxic mould growth at interface of lining and wall.

## Issues

- Not considered the effect on multiple other areas yet
  - Character
  - Over heating
  - Day lighting
  - Disturbance
  - Indoor air quality
  - Health
- Etc , etc

## Early Indications of Unintended Consequences

### Classification of UI

- Assessment process
- Systematic / Workmanship
- Occupant behaviour

### Scale of Consequence

- Minor
- Major
- Subjective

## Assessment

- Process to decide that insulation is the right measure. Understanding risk, exposure, condition of wall.
- Collection of the right data for the installers
- Choosing the right system – moisture, condensation, wind driven rain, pollution, aesthetics including heritage

## Systematic / Workmanship

- Weakness in the system , over reliance on sealant between 18 and 36 tubes per property.
- Insufficient checking of key stages
- Poor installation, poor standard industry details that create cold bridges
- Lack of understanding on correct application

## Issues

- Wrong expertise in the decision making
- Testing of materials in un realistic or unachievable conditions
- No consideration of actual UK climatic conditions
- Poor workmanship
- Little quality control evident on site – limited data
- Premature failure and underperformance of measures
